

Figure 1: Examples of loss of stability in bipedal and quadrupedal robots.

Stability is a significant issue for mobile robot design. Loss of stability can mean the robot is unable to move and must be reorientated or retrieved, which maybe difficult or impossible in some extreme environments, or in the worst case it can result in severe damage or destruction of the robot, and any objects it is carrying. This has become more of an issue as mobile robots have become increasingly fast and agile, often running [1], jumping [2] and hopping [3] around less controlled environments.

In many ways the consequences of stability loss in mobile robots are analogous to other situations. A human that falls over has to pick themselves up before continuing on, or if they are infirm they may require assistance. Likewise they could also suffer injury, or if walking along the edge of a long drop, fall to cause severe injury or death. A forklift truck or other piece of heavy plant can topple, injuring the driver and causing the damage or destruction of vehicles and materials.

In general, stability from a biomechanical perspective can be divided into two different types, *static* and *dynamic*. While there are numerous ways to define the difference between the two, such as the maximum lyupanov exponent for dynamic stability [4], the following definitions will be used:

- **Static** stability only considers the uniform force of gravity and assumes no other forces are acting on the object.
- **Dynamic** stability considers other forces and torques on the object, both internal and external, as well as gravity.

A stationary object that has no external forces or torques being applied needs to be statically stable, a moving object, or an object that is having a force or torque applied to it other than gravity, needs to be dynamically stable.

1 Static Stability

To determine if the robot is statically stable, the gravity axis projection of the center of gravity needs to fall within a defined “support polygon” on the plane perpendicular to the gravity axis plane, as in figure 3. If gravity is treated as a constant force along vector g , then the center of mass and center of gravity are equivalent. The center

Figure 2: Examples of loss of stability in a human and forklift truck.

of mass can be calculated for using equation 1 for n bodies of masses $m_{1...n}$ and COM positions $\mathbf{p}_{1...n}$. If the gravity vector is parallel to any of the basis vectors, then the perpendicular components of the COM/COG can be used to determine the static stability.

$$\text{COG} = \text{COM} = \frac{\sum_{i=1}^n m_i \mathbf{p}_i}{\sum_{i=1}^n m_i} \quad (1)$$

Fundamentally, there are two different methods to maintain static stability:

- Change the region or shape of the support polygon so the gravity axis projection of the center of gravity remains within the bounds of the support polygon.
- Move the gravity axis projection of the center of gravity so it remains within the bounds of the support polygon.

The former method can be considered equivalent to using a walking pole to steady yourself on uneven ground when hiking, the leg of the pole acts as a new vertex that is used to calculate the support polygon, expanding it

Figure 4: 2D representation of the ZMP of a legged robot under horizontal acceleration, with the support region defined by the contact points of the legs with the ground. Notice how increasing the horizontal acceleration of the robot can make it dynamically unstable.

sufficiently, or placing your foot in front of you when walking. The latter method can be considered equivalent to leaning back to remain upright when falling forward. Leaning back moves the centre of gravity to keep it within the support polygon.

However, just because the center of gravity falls outside of the support polygon does not mean that loss of stability is inevitable, as long as a force or torque applied to the body counteracts the forces and torques induced by the force of gravity in order to maintain stability. This is similar to applying a torque to your ankle when standing on one leg, or a strong wind keeping you upright when leaning forward. If this is the case, then *dynamic* stability is maintained while *static* stability is lost. If the force or torque is removed, then stability is lost. Conversely, forces and torques can also cause loss of stability even if the center of gravity does not fall outside of the support polygon. This is similar to being pushed over, or stopping too quickly and falling forward. So dynamic stability can maintain stability even if static stability is lost, but static stability cannot maintain stability if dynamic stability is lost.

2 Dynamic Stability

To determine if the robot is dynamically stable,

The concept of the Zero Moment Point, first defined in [], is useful for mobile robots to check if dynamic stability will be maintained. It extends the calculation used for static stability by including inertial forces caused by accelerations of the bodies, as shown in figure 4. Though it has mostly been utilised for bipedal robots to ensure stability while walking, it is also applicable to quadruped robots [], and has even been investigated for the development of a stability warning system in road vehicles [?]. The ZMP is formally defined as the point at which the point where the total of horizontal inertia and gravity forces equals zero. It can be thought of as a *dynamically augmented* version of the gravity axis projection of the center of mass.

Equation 2 defines the position of the ZMP for a robot or vehicle with n bodies of masses $m_{1...n}$, COM positions $\mathbf{p}_{1...n}$ and COM accelerations $\ddot{\mathbf{p}}_{1...n}$, in contact with a planar surface of normal vector \mathbf{n} (ZMP cannot be calculated for non-planar surfaces). $\boldsymbol{\tau}_{1...n}$ defines the torque acting on each COM, which can be calculated from .

$$\begin{aligned} \boldsymbol{\tau}_i &= \mathbf{R}_i \left(\mathbf{I}_i \ddot{\theta}_i - \left(\mathbf{I}_i \dot{\theta}_i \right) \times \dot{\theta}_i \right) \\ \text{ZMP} &= \frac{\mathbf{n} \times \sum_{i=1}^n (\mathbf{p}_i \times m_i \mathbf{g} - \mathbf{p}_i \times m_i \ddot{\mathbf{p}}_i - \boldsymbol{\tau}_i)}{\mathbf{n} \cdot ((\sum_{i=1}^n m_i \mathbf{g}) - (\sum_{i=1}^n m_i \ddot{\mathbf{p}}_i))} \end{aligned} \quad (2)$$

Figure 5: 2D representation of the static stability of a legged robot picking up a payload, with the support region defined by the contact points of the arm and legs with the ground. Notice how the payload acts as a contact point until it is lifted off the ground, preventing loss of stability even as the COM/COG is translated due to the mass of the payload.

3 Payload

When a payload is added to the robot, it is equivalent to instantaneously adding an extra body to the robot of mass m_p and position p_p thus changing the COM. Initially the payload will also create an extra contact point with the ground, changing the support polygon so the robot remains statically stable. However, as soon as contact between the payload and ground is severed, the robot can become statically unstable. This does not mean the robot will immediately lose stability, the dynamic forces created picking up the payload may keep the robot dynamically stable, but once the robot is stationary without other forces acting upon it, it may lose stability. The best way to compensate for this is to change the position of the other bodies so the COM remains within the support polygon. This is akin to leaning back when carrying something heavy. But leaning generally has limited range, so can only compensate for lighter payloads. An alternative is needed for heavy payloads.

4 Tails

Tails are a common sight in vertebrate animals, a natural extension of the spinal column. While some tails are used purely for grasping, communication or decoration, many have some function in maintaining stability. For example

4.1 Tails in Mobile Robotics

As many mobile robots have looked at animals for inspiration when it comes to solving various problems with dynamics and locomotion, tails have been used in the development of a significant selection of mobile robots. This is expanded further in section ??.
