I. INTRODUCTION

II. IMPROVEMENTS TO ORIGINAL DESIGN

A. Increasing AUJ Angle Range

The AUJ angle tracking experiments in [1] only had a range of $\pm 14.5^\circ$ in a single axis, and $\pm 6^\circ$ for both axes. This was because one or more twisted string actuator (TSA) would completely “unwind” near that limit and be unable to lengthen further. This limits the practicality of such a mechanism, for example a multi-segment design would have a very large minimum curvature. Increasing f_{\min} does increase the angle range marginally by increasing the TSA motor angle at $\theta = [0 \ 0]^\top$, \approx , as shown by experiments conducted on the original design in figure 1. These experiments were able to achieve modest increases of $4.004^\circ N^{-1}$ for the positive (upper) limit of the universal joint roll θ_1 , and $-6.062^\circ N^{-1}$ for the negative (lower) limit, within the f_{\min} interval [3, 3.5]. However, further attempts to increase f_{\min} , or attempts to perform the same experiment on the pitch axis resulted in premature string failure. It was also clear to achieve significant increases in AUJ angle range, a different approach would be needed that would require modifications to the design.

The most effective modification to improve AUJ angle range is to reduce the value of r in (??), as shown in figure 2. This decreases the stroke length required for each TSA to achieve the same AUJ angle range, which also reduces the TSA motor angle accordingly, allowing a greater AUJ angle to be reached before one or more TSA unwind. This can be done by using smaller motors, or by using the same size or larger motors with offset shafts

J. Carrasco and W. Heath are with the Department of Electrical and Electronic Engineering, School of Engineering, Faculty of Science and Engineering, The University of Manchester, Manchester, United Kingdom.

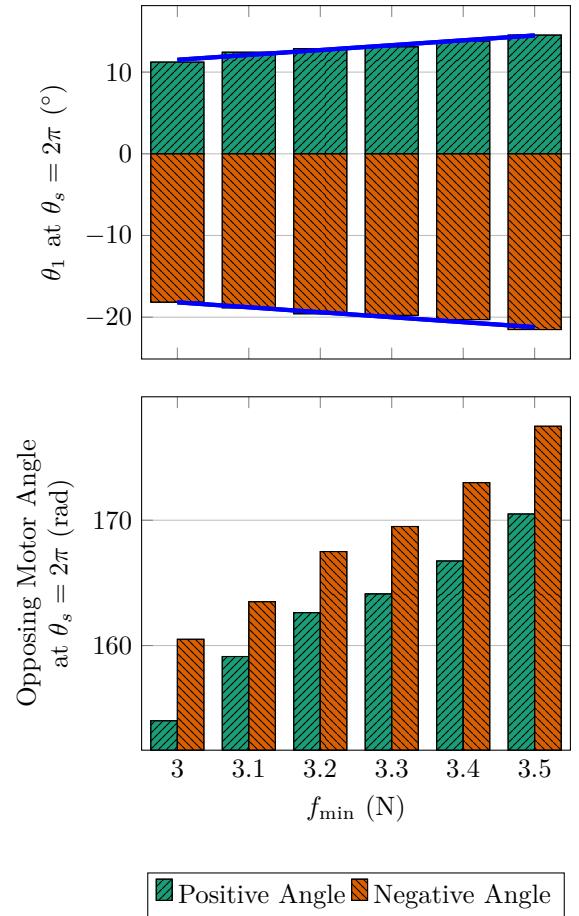

Fig. 1: AUJ roll angle (θ_1) when the smallest TSA motor angle is equal to 2π , and motor angle of the “opposing” TSA (the TSA with the largest motor angle) at the same position.

connected by spur gears. Smaller motors were chosen, with a cross section of only 120 mm^2 compared to 227 mm^2 for the existing design. These were Guangdong Kingly Gear Co. Micro Metal Gearmotors (50:1), [2] which were low cost so could be easily replaced if damaged, were lighter than the existing motors, 18 g compared to 27 g, and the mechanism would be less complex. These motors have a θ_{\max} lower than the existing motors of

only 44 rad s^{-1} compared to 442 rad s^{-1} [3], but since the original experiments limited the motor velocity to rad s^{-1} to ensure mechanism stability, this is not a concern. This change of motors allowed r to be reduced from 13 mm to 7.25 mm, as shown in figure ??.

In order to facilitate this reduction, other alterations to the design were required. The distance between the TSA strings was now too small to have a central shaft in the middle, as was the case in the original design. Instead of having a central shaft for the universal joint, the universal joint was constructed around the TSA with a “hollow spider” arrangement, where the TSA strings pass through a hole in the middle of the universal joint, as illustrated in figure 3. This also meant there was enough space to allow the installation of AUJ angle sensors directly onto the universal joint, which are discussed in section II-B.

B. Improving AUJ Angle Measurement Accuracy

The original design used a Bosch Sensortec BNO080 9 degree of freedom (DOF) inertial measurement unit (IMU) [4] to measure the AUJ orientation. Originally it was planned for a pair of these IMU to be used, one on the base segment and one on the follower segment, and the orientation of the AUJ to be calculated from the difference between them in any orientation. However, the magnetometer measurements proved to be unreliable inside the laboratory, so only a single IMU was used and the base segment was orientated with the gravity vector parallel to the z axis. This allowed the AUJ orientation to be calculated from only the accelerometer readings, but meant the mechanism could only be controlled when orientated in the vertical axis.

There was also an issue with the IMU resolution as shown in figure ??, which is only only accurate to within 0° . A Savitsky-Golay filter was applied to the results in [1] for data presentation purposes and to more accurately represent the true AUJ angles at that point in time.

In order to allow the mechanism to be controllable for any orientation with respect to gravity, a solution that could directly measure the mechanical angular displacement of the universal joint was needed. Two options were considered, potentiometers and hall effect sensors. A potentiometer would couple a shaft of each universal joint spider axes to a resistive track, changing its resistance depending on AUJ orientation and providing an analog voltage signal to the controller. A hall effect sensor would be similar to the potentiometer solution, but would use a radially bipolar magnet on the end of the shaft with a hall effect sensor beneath it, which would also provide an analog voltage signal or digital data for the axial orientation of the magnet, and therefore the shaft [5]. The potentiometer solution was chosen for easy availability of components and simplicity of control integration, since no programming of the sensor would be required. The potentiometer also has mechanical stops, which make it easier to assure the required AUJ angle range will be able to be measured during assembly. The hall effect sensor is

continuous, and the measured voltage overflows every 180° [5], so it would be very important to ensure the magnet was initially oriented at a value that would encompass both the maximum and minimum joint limit for each AUJ axis. The Bourns PDB08 was selected as the potentiometer due to its small size and internally threaded shaft, which would allow a captive bolt to be inserted as the spider shaft [6]. As a voltage divider at $+5 \text{ V}$, the PDB08 would have a resolution of approximately 40° V^{-1} . With the 12-bit resolution of the onboard analog to digital converter (ADC) for myRIO analog inputs, this gives a theoretical resolution of $\approx 0.048^\circ$. The potentiometer sliding noise (max. 100 mV) will reduce this during AUJ motion, however this can be partially mitigated with filtering.

C. Preventing String Failure

One reoccurring issue with the original experiments were the TSA strings breaking at high values of θ_s , which became more common after a number of twisting and untwisting cycles. Occasionally this was caused by the mechanism operating beyond expected limits for θ_s and f due to a failure of limit monitoring within the control system, but failure would also occur within normal operating conditions.

Analysis of the design and the location of the string failures identified “pinch points” and “bite points”, as shown in figure 4a, which could potentially damage the string under high tension, causing it to thin out and lose integrity. By removing these points, by rounding off sharp edges and using an alternative method to secure the string, tying it into a loop instead of using grub screws, eliminated these potential sources of string damage, as shown in figure 4b. However, nylon monofilament, as was used for the TSA string, is still susceptible to torsion fatigue [7], [8] which reduces tensile strength [9]. This means the monofilament string will be increasingly susceptible to failure with more twisting and untwisting cycles. Therefore, the SeaKnight BLADE 0.2 mm nylon monofilament was exchanged for 0.2 mm Dyneema[®] polyfilament string, as used in [10]. Changes to the design of the string clamp allowed for easier installation of string filament, making polyfilament string a practical option.

III. EXPERIMENTAL RESULTS

A. AUJ Angle Tracking

B. The Effect of Follower Mass on AUJ Angle Tracking

Figure 6 shows the setpoint and response trajectory for each experiment for both version 1 and version 2. Initially, k_p was set to the same value as in table ??, however the system was unable to reach a steady state in any configuration other than “No Mass”. Reducing k_p to 1000 in the weighted configurations solved the steady state issue and resulted in an average maximum tracking error of 0° over all configurations with added mass, similar to the result from the initial experiments. However, for the “No Mass” configuration, $k_p = 8000$ resulted in a very poor tracking response, whereas k_p from table ??

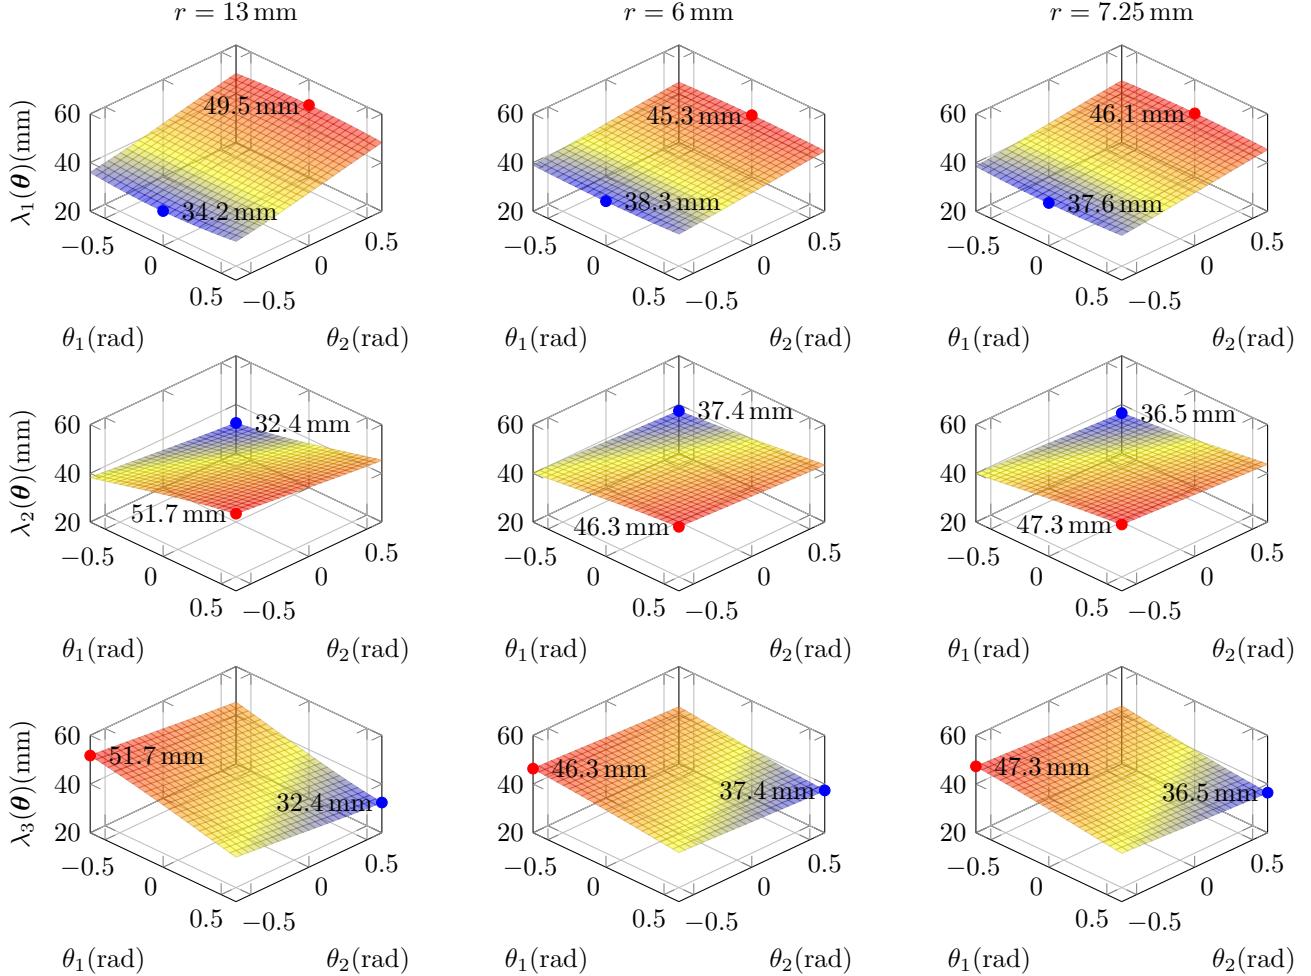

Fig. 2: Surface plots, minima and maxima for the lengths of $\lambda_{1,2,3}$ at $r = 13 \text{ mm}$, $r = 6 \text{ mm}$ and $r = 7.25 \text{ mm}$ in the range $[-\frac{\pi}{5}, \frac{\pi}{5}]$. As r decreases, the difference between the minima and maxima also decreases. This means that a lower value of r requires a smaller stroke range of the TSA for a given AUJ angle range.

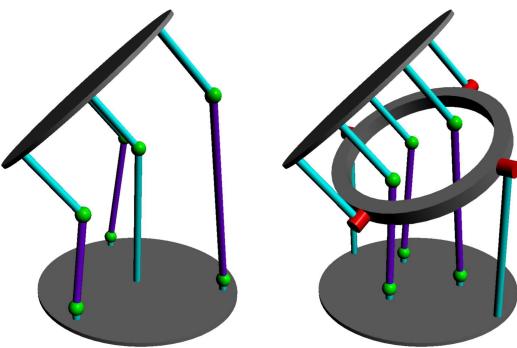

Fig. 3: An AUJ with a central universal joint, and one with a hollow spider. The hollow spider allows r to be decreased as space is no longer required for a central universal joint.

resulted in a maximum tracking error of 0° , once again similar to the result from the initial experiments. In future implementations gain scheduling can be employed to select the most optimal k_p for a given follower mass, that allows for the smallest tracking error while being able to reach a

steady state.

IV. DISCUSSION

A. active transmission adjustment (ATA)

B. Dynamics Gravity Vector

In the experiments, the gravity vector \mathbf{g} was assumed to be parallel to the z axis ($[0 \ 0 \ -9.81]$) since the experiments were conducted in a vertical orientation. To operate in any other orientation, the gravity vector would need to be calculated using an IMU (gyroscopes would be required to compensate for forces generated using motion).

C. Load Cell Limitation

As seen in section ?? and ??, the load on each TSA being limited to 9 N meant that the AUJ angle range limited both with an increased follower mass and dual axis. Using load cells with a larger full scale would increase the AUJ angle range in both cases.

TABLE I: Table of all the follower mass configurations, with the parameters for follower mass m and follower COM z offset ρ_3 .

Configuration	m [g]	ρ_3 [mm]	I [kg m $^{-2}$]	Image
No Mass	62	3.1	$\begin{bmatrix} 3.3 \times 10^{-5} & 0 & 0 \\ 0 & 3.1 \times 10^{-5} & 0 \\ 0 & 0 & 1.4 \times 10^{-5} \end{bmatrix}$	
+20.0 g	160	35	$\begin{bmatrix} 1.3 \times 10^{-4} & 0 & 0 \\ 0 & 1.3 \times 10^{-4} & 0 \\ 0 & 0 & 4.6 \times 10^{-5} \end{bmatrix}$	
+50.0 g	260	43	$\begin{bmatrix} 1.7 \times 10^{-4} & 0 & 0 \\ 0 & 1.7 \times 10^{-4} & 0 \\ 0 & 0 & 7.7 \times 10^{-5} \end{bmatrix}$	
+80.0 g	360	46	$\begin{bmatrix} 2.0 \times 10^{-4} & 0 & 0 \\ 0 & 2.0 \times 10^{-4} & 0 \\ 0 & 0 & 1.1 \times 10^{-4} \end{bmatrix}$	

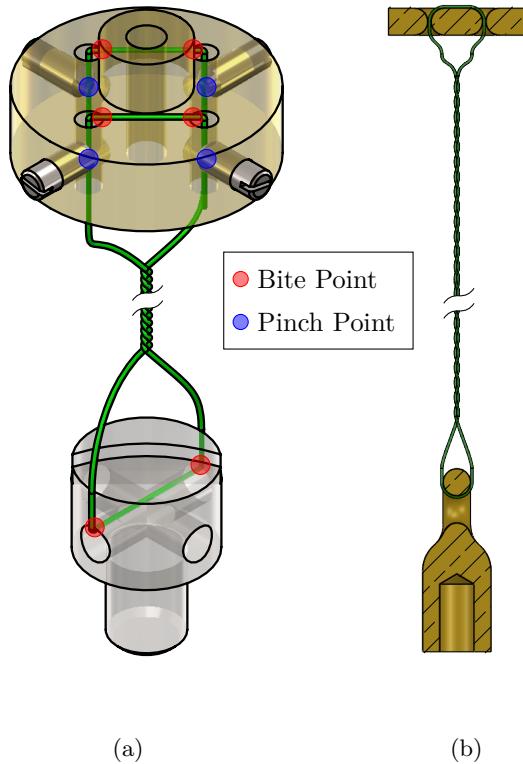

Fig. 4: (a) The original TSA string loop between the string clamp and capstan bolt, with “pinch” and “bite” points indicated, where premature string failure may occur. (b) Section view of the new TSA string loop showing how these pinch and bite points have been eliminated.

D. Multi-Segment Design

A distributed embedded control system in each segment, as shown in figure ??, could receive AUJ angle position setpoint commands from a “primary” controller. This would allow for complex trajectories to be executed while allowing the segments to share a common power and communication bus, reducing wiring complexity and allowing for a modular design.

V. CONCLUSION

VI. ACKNOWLEDGEMENT

This work was supported by a UKRI EPSRC Doctoral Training Partnership [1957210], and by the UKRI Strength in Place Fund [84646 (AMPI)]. The lead author also wishes to thank Dr. Dmitriy Makhnovskiy for his assistance in preliminary research for this publication.

Dr. Damian J. Crosby is a Post Doctoral Research Associate in the Department of Mechanical, Aerospace and Civil Engineering, University of Manchester, U.K. He received a B.Sc. in Special Effects Development from The University of Bolton, U.K., in 2010, and a M.Res. in Robotics from The University of Plymouth, U.K., in 2012. He worked as a Research Technician in robotic laser welding at The University of Manchester from 2013 to 2017, and then completed his PhD at the same university in 2023, developing a robotic tail for improved robot balance when carrying a payload. He has worked on robotic research in the fields of nuclear energy and advanced manufacturing.

Dr. Joaquin Carrasco is a Lecturer at the Department of Electrical and Electronic Engineering, University of Manchester, UK. He was born in Abarn, Spain, in 1978. He received the B.Sc. degree in physics and the Ph.D. degree in control engineering from the University of Murcia, Murcia, Spain, in 2004 and 2009, respectively. From 2009 to 2010, he was with the Institute of Measurement and Automatic Control, Leibniz Universitt Hannover, Hannover, Germany. From 2010 to 2011, he was a Research Associate at the Control Systems Centre, School of Electrical and Electronic Engineering, University of Manchester, UK.

Prof. William P. Heath is Chair of Feedback and Control in the Department of Electrical and Electronic Engineering, University of Manchester, U.K. He received the B.A. and M.A. degrees in mathematics from Cambridge University, U.K., in 1987 and 1991, and the M.Sc. and Ph.D. degrees in systems and control from the University of Manchester Institute of Science and Technology, U.K., in 1989 and 1992, respectively. He was with Lucas Automotive from 1995 to 1998 and was a Research Academic at the University of Newcastle, Australia from 1998 to 2004. His research interests include absolute stability, multiplier theory, constrained control, and system identification.

Prof. Andrew Weightman graduated in 2006 with a PhD in Mechanical Engineering from the University of Leeds. Whilst at the University of Leeds he developed rehabilitation robotic technology for improving upper limb function in adults and children with neurological impairment which was successfully utilised in homes, schools and clinical settings. In 2013 he moved to the University of Manchester, Department of Mechanical, Aerospace and Civil Engineering as a Lecturer in Medical Mechatronics. Prof. Weightman has research interests in biomimetic mobile robotics, rehabilitation robotics, robotics for nuclear decommissioning and collaborative robotics.
